Abstract
Winter-sport participation may be associated with a risk of injuries. The article provides a brief overview of the epidemiology of winter-sports-related trauma, referring to common skiing and snowboarding injuries in professional athletes or inexperienced ones (amateurs), to determine injury patterns, crash circumstances, their pathological repercussions, and possible preventive interventions. Known risk factors for the occurrence of injuries are: lack of experience in snow-sports, suboptimal skill and technical level, poor physical fitness level, fatigue, risk-taking behavior, alcohol consumption, absence or rented and/or faulty equipment and protective devices, high speed, ice on the slope, bad weather conditions and poor visibility, crowd on the track. This short exposure aims to educate younger (recreational) skiers and snowboarders to prevent traumatic injuries to the limbs and especially the catastrophic ones, resulting in central nervous system lesions, with devastating consequences for athletes, their families, and communities. The paper has a multidisciplinary addressability: it may be useful for general practitioners and young specialists in orthopedics, neurology, physical medicine & rehabilitation, and kinetotherapy.

Key words: winter sports; snowboarding injuries; skiing injuries; bobsleigh; luge; skeleton; spinal cord injury; traumatic brain injury; injury prevention; physical disability,

Introduction
Being active in sports has many positive health effects, and provides many benefits to physical and mental health. The Latins had a famous proverb: “Mens sana in corpore sano / A sound mind in a healthy body”.

Recreational or professional alpine skiing, snowboarding, luge, are increasing in popularity worldwide, enjoyed by millions of participants of all ages and skill levels. In 2010 an estimated 11.5 million people in the United States participated in skiing, and 8.2 million engaged in snowboarding (1). Besides the beneficial health effects of an active life style, sport participation may be unfortunately associated with risk of injuries.

Sometimes devastating traumatic injuries can have dramatically consequences for the athletes, their families, and communities. Severe post traumatic neurological injuries can raise significant public health concern, and even may discourage participation in sport. Michael Schumacher’s dramatic fate was an intensely covered topic in mass-media, five years ago.

Material and Method
A systematic search of Pubmed Database focused on the above-mentioned keywords was conducted to identify relevant articles and systematic reviews published in English literature, reporting winter-sport related accidents. This article is a short overview of the epidemiology of snow sport-related trauma, referring to the common skiing and snowboarding injuries in professional athletes or inexperienced (amateurs) tourists, to determine the injury patterns, crash circumstances, their pathological repercussions, and possible preventive interventions.

Known risk factors for the occurrence of injuries are lack of experience in snow-sports, technical errors, suboptimal technical level and poor physical fitness level, fatigue, risk-taking behavior, and alcohol consumption, presence of ice on the slope, bad weather conditions and poor visibility, crowd on the track, high speed, rented or faulty equipment or protective devices (2,3,4).

Local mountaineers ironically and generically call a category of amateurs, inexperienced athletes, as "paltonari" (term derived from “palton”, similar to the English word “paletot”), referring to their unfit
mountain equipment and imprudent behavior. These inexperienced skiers and snowboarders are usually exuberant and defiant young persons, predisposed to alcohol consumption and risk-taking behavior with dramatic repercussions (severe limb fractures or catastrophic neurologic injuries). Recent international literature reviews emphasize that the incidence of traumatic brain injury (TBI) and spinal cord injury (SCI) in winter sport activities are increasing, mainly in alpine skiing and snowboarding (5,38). Although uncommon, fatal and severe nonfatal (but with dramatic debilitating sequels) brain and spine injuries can occur during winter-sports, and induce enormous financial burden to society. These accidents may happen at all levels of play, from youth to professional athletes (6, 7). In Canada, all winter sports injuries are responsible for significant health care burden, with estimates of $400 million in direct and indirect annual health care costs (8).

Catastrophic spinal injuries in sports are rare but tragic events, and athletic competition has long been a known source of spinal cord injuries (SCIs). SCI is a rare but serious event and a major cause of morbidity and mortality for skiers and snowboarders. Approximately 8.7% of all new cases of SCIs in the United States are related to (general) sports activities; ice hockey, skiing and snowboarding are among the highest risk-spots for SCIs (7). Spine trauma is among the most devastating injuries in snow sports, comprising 1% to 17% of all injuries in skiers and snowboarders (9, 10). Different epidemiological studies emphasized that most SCIs occurred after intentional jumps, rather than collisions (11, 12).

In 13.4% patients, most commonly seen are “tandem injuries”: a closed head injury and cervical spine trauma, with possible catastrophic repercussions (13). Safety helmets decrease the risk for and the severity of head injuries. Although helmets do not protect the spine, they certainly do not increase the risk of neck and cervical injuries (14, 15).

The common mechanism of SCI for all at-risk winter sports is represented by an axial compression force to the top of the head with the neck in neutral position of slightly flexed (7). The biomechanical dynamic proprieties of the head and spine, the force vector applied during impact, the intrinsic strength and anatomy of vertebral bodies and their surrounding spinal elements (16) concur to SCI. In neutral, vertical position, the average weight of human head is around 4.5 to 5 kg at rest. As the head is bending forward, its weigh increases from 13 kg (at 15°), to 20 kg (at 30°), 24.5 kg (at 45°), 30 kg (at 60°) (17). These biomechanical variable factors may explain a cervical SCI after an accidental fall on the ischial tuberosities.

Spinal injury patterns among snowboarders and skiers associated cervical spine trauma in 19.6% cases vs. 10.9% of thoracic and 6% of lumbar injuries (13).

A systematic review of published literature (1980 - 2015) reporting the epidemiology of sport-related SCIs emphasized that the greatest majority of cervical SCIs were encountered in hockey and skiing, whereas in snowboarding over half of the spinal lesions were fond with predilection in the thoracic or lumbosacral levels (18). In snowboarders falling backward represent the mechanism of spine injury (typically in the fragile thoracolumbar junction), causing an axial load or a flexion-distraction moment (11, 19).

Lower trunk lesions (pelvis, hip, lumbar spine) are usually characteristic of snowboarders (20). Acrobatic jumping or accidental collisions with trees or ski towers are responsible for snowboarding-related pelvic ring fractures, associated or not with sacral fractures. Incidence of pelvic fractures was 2%, and in about 14.5% patients have occurred axial biomechanical stability problems (21).

Pending of the vertebral lesion and neurological level of injury, immediate and sometimes life-long catastrophic neurological consequences can occur: more or less severe paralysis of the entire body (tetraplegia), or only paralysis of the lower limbs (paraplegia), infra-lesional anesthesia, neurogenic bladder requiring artificial voiding (using indwelling or intermittent urinary probes), neurogenic bowel, respiratory dysfunction, predisposition to pressure ulcers, pulmonary or urinary infections.

Another catastrophic winter-sport event is TBI, the leading cause of death and severe disability in skiing and snowboarding. Approximately 600,000 ski- and snowboarding-related injuries occur in North America each year, and head trauma accounts for 20% of all injuries (14).

Amateurs (“week-end athletes”) aged between 46 to 55 years, and those who never had a professional instruction, or those with rented equipment are predisposed to catastrophic neurological lesions (22). Cerebral trauma was reported in 28% of all ski injuries, respectively in 15% (23) up to 33.5% (24) of all reported snowboarding injuries.
One must stress that TBI can have fatal outcomes among snowboarders and skiers of all ages, and is the culprit for up to 88% of all winter sport-related deaths (14). Little research has been conducted on sport-related concussion and injury prevention strategies in competitive sledding sports, like bobsleigh, luge, and skeleton. Skeleton is a winter sliding sport in which a person rides a small sled, known as a skeleton bobsled (or sleigh), down a frozen track, while lying face down and head-first (25). Prevention strategies are limited, with no possibility of attenuating a catastrophic collision to the head, by interposing the hands. Concussions are a common occurrence in elite sledding sport athletes, affecting 13-18% of all, and this risk factor was entitled "sled head" (26).

Recreational sledding (tobogganing), very popular in Alpine regions, consists in ascending and sledding down on the same track. Apparently safe and stable, about 9% participants reported sledding-related injuries to: lower extremities (41%), arms (22%), shoulder and back (11%), or head (10%) (4).

Overall, 22% of head injuries can be serious enough to cause clinical signs of concussion (14); acute subdural hematoma represents the most common neurosurgical indication for intervention (27). Immediate consequences can be devastating, consisting of serious neurological and psychological disorders: different degrees of alteration of the cognitive and executive functions, aphasia, hemiplegia or even tetraplegia, neurogenic bladder, vegetative status and feeding by percutaneous endoscopic gastrostomy (PEG). Unfortunately, most of these severe impairments may persist as life-long disabilities. Due to the violent energy impact, head trauma is the leading cause of mortality after injuries related to skiing and snowboarding (15).

Due to actual objective limitations of therapeutic possibilities of intervention to restore neurological function after TBI and SCI, the best treatment is prevention. Safety helmets are strongly recommended during recreational skiing and snowboarding (14). There is evidence that helmets reduce the risk of head injury by 22-60% (5).

In Netherlands was developed an evidence-based tailored Web-based advice tool (Wintersportklaar) for online intervention, addressed to skiers and snowboarders. It promotes adequate protection equipment, correct information and sustained media education initiatives advocating injury preventive behavioral attitude essential to counteract the “adverse effects” of winter-sports (28).

Severe injuries are more common in snowboarding accidents. Referring to snowboarders: wrist injuries, shoulder soft tissue injuries, ankle injuries, concussions, and clavicle fractures were most frequently seen, whereas in skiers anterior cruciate ligament (ACL) sprain or tear, medial collateral ligament (MCL) sprains, or lateral collateral ligament (LCL) sprains of the knee, lower extremity contusions, and tibia fractures were mostly encountered (1, 19, 29).

Shoulder injuries were reported in 4 to 11% of all alpine skiing injuries and in 22 to 41% of all upper-extremity ones (31). During snowboarding, shoulder girdle injuries account for 8 to 16% of all injuries and for 20 to 34% of all upper-extremity ones (1, 30).

Most common shoulder injuries during skiing and snowboarding were [30]: glenohumeral dislocations (5.5% of all injuries) (21), rotator cuff strains, acromioclavicular dislocation, and clavicle fractures (4% of all reported injuries) (9,1).

Falls, in addition to pole planting during skiing and aerial maneuvers during snowboarding are the most common causes of shoulder injury (31).

Overall, upper limb injuries in snowboarding have a double frequency, compared to those registered during alpine skiing (22, 29). Most common fractures were noticed at the radius (48%), clavicle (11%), humerus (11%), and ulna (7-8%) (32).

Shoulder injuries were reported in 4 to 11% of all alpine skiing injuries and in 22 to 41% of all upper-extremity ones (31). During snowboarding, shoulder girdle injuries account for 8 to 16% of all injuries and for 20 to 34% of all upper-extremity ones (1, 30).

Falls, in addition to pole planting during skiing and aerial maneuvers during snowboarding are the most common causes of shoulder injury (31).

Overall, upper limb injuries in snowboarding have a double frequency, compared to those registered during alpine skiing (22, 29). Most common fractures were noticed at the radius (48%), clavicle (11%), humerus (11%), and ulna (7-8%) (32).

Wrist represents the most common location of upper extremity injuries related to snowboarding, accounting for 32% (33) - up to 44% of all upper extremity injuries (34), and fractures accounted for 31% (33) - up to 78% of total wrist lesions (34).

Snowboarding-related wrist lesions registered between 2010 to 2016 in the emergency departments in the United States included wrist strains/sprains (25.2%), contusions (10.9%), concussions (10.0%), and dislocations (4.0%) (34).

Usually beginner snowboarders are predisposed to falling and wrist fractures. Snowboarding-related hand injuries accounted for 8.4% of the total upper extremity lesions (34).
The natural defense reflex during falling down represents the physiopathological mechanism of the shoulder and/or wrist injuries. The severity of arm injuries in snowboarding seems to be caused by direct force on the wrist and elbow, which receive the full impact of a fall (29). Analyzing the falling kinematic mechanisms one emphasized that falling backward leads to a wrist injury, whereas a fall forward (toe side) is more predictive of a shoulder injury (19). These aspects explain why upper extremities fractures in snowboarders are three times more common than in skiers, affecting mainly the left upper extremity, with the exception of wrist fractures (35).

**Knee** is the most common region of the lower extremity injured during skiing, with a mean incidence of 42 injuries per 1,000,000 person-years, and a higher incidence in adults, mainly in males (46 per 1,000,000 person-years) (20).

The anterior cruciate ligament (ACL) is involved in approximately 50% of all knee serious injuries, due to forced internal rotation and/or valgus loading, in the effort to restore the trajectory of the skis (36). It is frequently associated with concomitant (other) injuries, such as medial collateral ligament (MCL) sprains, meniscal tears, or tibial plateau fractures (36).

**Foot and ankle** injuries (ankle fractures and sprains) are most prevalent type of injuries associated with snowboarding, estimated at 15% of all lesions encountered in this sport (37). Fracture of the lateral process of the talus is relatively unique to snowboarding, and is commonly called the "snowboarder's fracture" (37). The greatest majority of snowboard-related lesions were encountered in persons who did not have a correct initial instruction from professional staff (93%) and did not use protective equipment (87%) (35). Sustained information on specific technical procedures and biomechanical particularities in each winter sport, the correct application of the learned techniques on the slopes, and the encouragement of adequate use of protective equipment are mandatory to avoid possible serious accidents.

This short exposure aims educational approach to stimulate injury preventive behavior among amateur skiers and snowboarders. In a beautiful lyric song Jacques Brel said: “On a beau faire on a beau dire, Qu’un homme averti en vaut deux “/ An informed man is worth two!”

**Conclusion**

In conclusion, referring to winter-sport related catastrophic lesions of the central nervous system, PREVENTION IS CURE!

**Disclosures** The author has no conflicts of interest to disclose.

**Abbreviations**

- ACL, anterior cruciate ligament
- LCL, lateral collateral ligament
- MCL, medial collateral ligament
- SCI, spinal cord injury
- TBI, traumatic brain injury
